FINTECH · DIGITAL PAYMENTS

Razorpay – Digital Payment & Transaction Analytics Dashboard

MySQL · Power Query · DAX · Power BI

Priya Dharshini S | Anudip Foundation | DBA_AI | Batch ANP-D7635

02 Agenda

01 Project overview

02 Dataset

03 Tools & technologies

04 Workflow & SQL work

05 KPIs explained

06 Three Power BI dashboards

07 Key insights

08 Learnings & next steps

03 What is this project about?

The problem

A payment company records thousands of transactions with many details: amount, payment method, status, fees, location and refunds. Reading them field by field makes it hard to understand how payments are really performing.

My solution

In one line: I turned raw payment data into three easy dashboards.

04 About the Dataset

1,500	28	INR	Jan–Oct 2026
Transactions (rows)	Columns	Currency	Time period

- Name: Razorpay Digital Payment Analytics Dataset
- Synthetic (practice) data – not official Razorpay data
- Stored in MySQL: database razorpay_analytics, table razorpay_working_dataset
- Main columns: Amount, Status, Payment Method, Failure Reason, Refund Amount, Customer Type, Merchant Type, Fee

05

Tools & Technologies

MySQL

Database creation, record count and preview

Power Query

Data cleaning and transformation

DAX

KPI measures and calculations

Power BI Desktop

Dashboards and visualisation

CSV

Dataset file format used for import

In one line: Store → Clean → Calculate → Show.

06

How I Built It – Workflow

1. CSV Data

Collected the dataset

2. MySQL

Stored and checked records

3. Power Query

Cleaned and prepared data

4. DAX

Created KPI measures

5. Power BI

Built 3 dashboards

6. Insights

Explained the findings

In one line: Data → Database → Clean → Measures → Dashboard → Insights.

07 SQL Work in MySQL

```
CREATE DATABASE razorpay_analytics;

USE razorpay_analytics;

SELECT COUNT(*) AS total_transactions
FROM razorpay_working_dataset;

SELECT *
FROM razorpay_working_dataset
LIMIT 10;
```

Create the database

Select it for use

Count rows → 1,500

Preview first 10 rows

08 KPIs Explained in Simple Words

Total Transactions	Count of all payment records	**1,500**
Transaction Value	Sum of the Amount column	**₹18.98M**
Success Rate	Successful ÷ total = 1,004 ÷ 1,500	**66.9%**
Failed Transactions	Count of records with Failed status	**255**
Transaction Fees	Sum of the fee column	**₹189.8K**

09

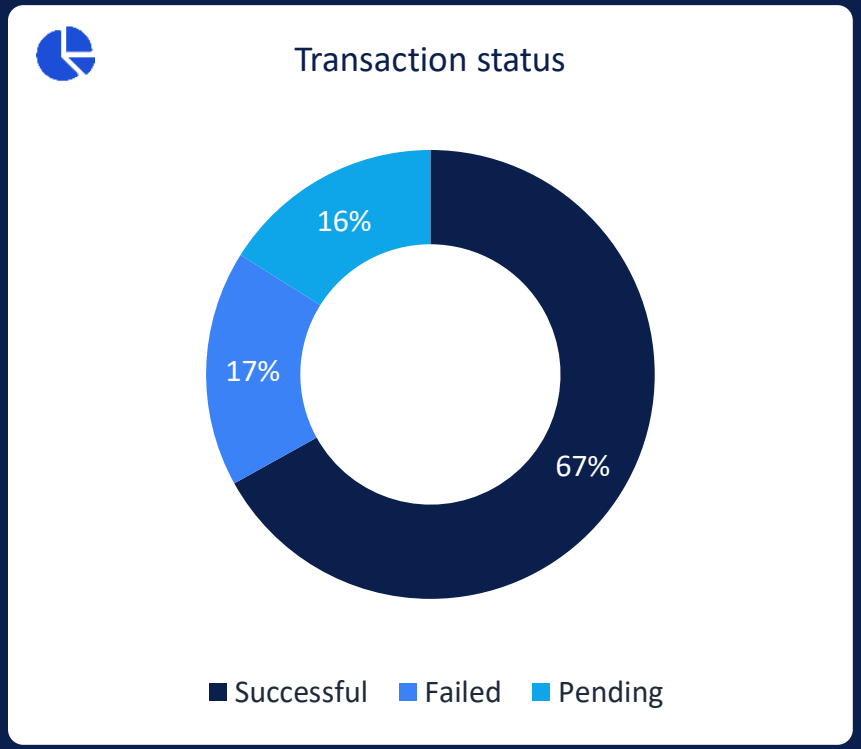

Dashboard 1 – Executive Overview

1.5K	18.98M	66.9%	255	189.82K
Total transactions	Transaction value (₹)	Success rate	Failed	Total fees (₹)

- Shows payments by month, payment method and status
- Shows which states and cities have the most transaction value
- Month slicer: click a month and all charts update

In one line: Quick health check of all payments in one page.

Dashboard 2 – Payment Performance

1,004
Successful

255
Failed

241
Pending

- About 67 of every 100 payments succeeded
- About 17 failed and 16 are pending
- Also shows failure reasons and fees by payment method

11 Dashboard 3 – Customers & Refunds

~1.5K	376	2.05M	189
Total customers (card)	New customers	Total refunds (₹)	Refund transactions

- Refund amount by status and month
- New vs existing customers
- Merchant types and transactions by state
- Data has 433 unique customer IDs, while the customer card shows ~1.5K

12 Key Insights

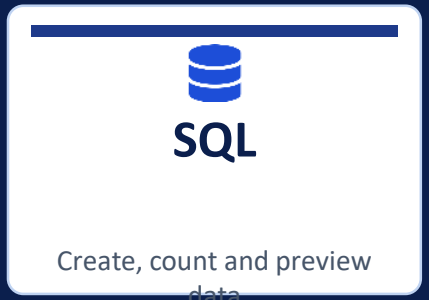

₹18.98M
Total transaction value

₹189.8K
Total fees

₹2.05M
Total refunds

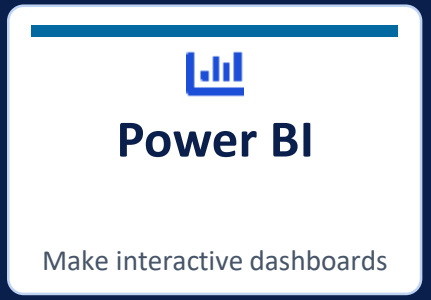

- Success rate is about 66.9% – roughly 2 in 3 payments
- 255 payments failed and 241 are still pending
- Pending counts as not-successful: if pending is excluded, success is about 79.7% (1,004 of 1,259)
- 189 transactions had a refund
- Practice data, so results are not real Razorpay performance

13 What I Learned & Next Steps

- Built an end-to-end payment analytics project
- Three dashboards cover transactions, payments, customers and refunds
- Next steps: unique-customer KPI (433 IDs), more SQL analysis, live data

Thank You

Questions are welcome
